Preface

Purpose

This *Progress Database Design Guide* is intended to provide a comprehensive, authoritative reference for database designers and developers using Progress 4GL. It covers the design and implementation of databases, including the use of the Progress 4GL environment, the Progress 4GL database engine, and the Progress 4GL database API. The guide is intended for use by database designers and developers who are working with Progress 4GL.

Audience

This guide is intended for database designers and developers who are working with Progress 4GL. It is intended for use by database designers and developers who are working with Progress 4GL.

Organization of This Manual

Chapter 1, Introduction
This chapter provides an overview of the Progress 4GL database engine and the Progress 4GL database API. It covers the basic concepts of database design and implementation, including the use of the Progress 4GL environment, the Progress 4GL database engine, and the Progress 4GL database API. It also covers the basic concepts of database design and implementation, including the use of the Progress 4GL environment, the Progress 4GL database engine, and the Progress 4GL database API.

Chapter 2, Tutorial
This chapter provides a tutorial for database designers and developers who are working with Progress 4GL. It covers the basic concepts of database design and implementation, including the use of the Progress 4GL environment, the Progress 4GL database engine, and the Progress 4GL database API. It also covers the basic concepts of database design and implementation, including the use of the Progress 4GL environment, the Progress 4GL database engine, and the Progress 4GL database API.

1.3 Elements of a Relational Database

R E.F.C T relational model
() ;
(), (), T

1.3.1 Tables

A table

is a collection of data organized in a grid.

Figure 1-1

Column (Fields)		
Cust Number	Name	Street
101	Jones, Sue	2 Mill Ave.
102	Hand, Jim	12 Dudley St.
103	Lee, Sandy	45 School St.
104	Tan, Steve	77 Main St.

Row (Records)

Figure 1-1: Columns and Rows in the Customer Table

Each row represents a customer record. The columns are labeled Cust Number, Name, and Street.

1.3.2 Rows

A row (record) is a horizontal line of data. Each row represents a single customer. The columns are labeled Cust Number, Name, and Street.

1.3.3 Columns

Each column represents a specific attribute of the customer. The columns are labeled Cust Number, Name, and Street.

1.3.4 Keys

Table: A primary key is a set of one or more columns in a table that uniquely identifies each row in the table. A primary key is defined by the `PRIMARY KEY` constraint. For example, in the `EMPLOYEE` table, the `EMPLOYEE_ID` column is the primary key.

- Mandatory:** A primary key is mandatory, meaning that every row in the table must have a value for the primary key column(s).
- Unique:** A primary key is unique, meaning that no two rows in the table can have the same value for the primary key column(s). For example, in the `EMPLOYEE` table, the `EMPLOYEE_ID` column is unique.
- Stable:** A primary key is stable, meaning that the value for the primary key column(s) does not change over time. For example, in the `EMPLOYEE` table, the `EMPLOYEE_ID` column is stable.
- Short:** A primary key is short, meaning that the primary key column(s) is/are short. For example, in the `EMPLOYEE` table, the `EMPLOYEE_ID` column is short.

NOTE: A foreign key is a set of one or more columns in a table that references the primary key of another table. A foreign key is defined by the `FOREIGN KEY` constraint. For example, in the `DEPARTMENT` table, the `DEPARTMENT_ID` column is a foreign key that references the `DEPARTMENT_ID` column in the `EMPLOYEE` table.

A composite key is a primary key that consists of two or more columns.

Indexes

A index is a data structure that improves the speed of retrieval operations on a database table. An index is defined by the `INDEX` constraint. For example, in the `EMPLOYEE` table, the `EMPLOYEE_ID` column is indexed.

3.4 Physical Database Design

The physical database design

is a design that is based on the logical design.

- It is a design that is based on the logical design.
- It is a design that is based on the logical design.
- It is a design that is based on the logical design.
- It is a design that is based on the logical design.

Denormalizing

is a process of removing the normalization constraints from a database. It is used to improve the performance of a database by reducing the number of joins that are required to retrieve data. It is often used in data warehouses and other systems where the data is read more often than it is written.

Table 3-1: Order Table with Derived Column

Order Number (Primary Key)	Order Date	Order Amount	Total After Tax	Cust Num (Foreign Key)
M31	3/19/91	\$400.87	\$441.74	101
M98	8/13/91	\$3,000.90	\$3,300.99	101
M129	2/9/91	\$919.45	\$1,011.39	101
M56	5/14/90	\$1,000.50	\$1,100.55	102
M37	12/25/90	\$299.89	\$329.87	103
M140	3/15/91	\$299.89	\$329.87	103
M41	4/2/90	\$2,300.56	\$2,530.61	104

3.5 Physical Implementation

Defining Indexes

T

4.1 Overview

4.2 Indexing Databases

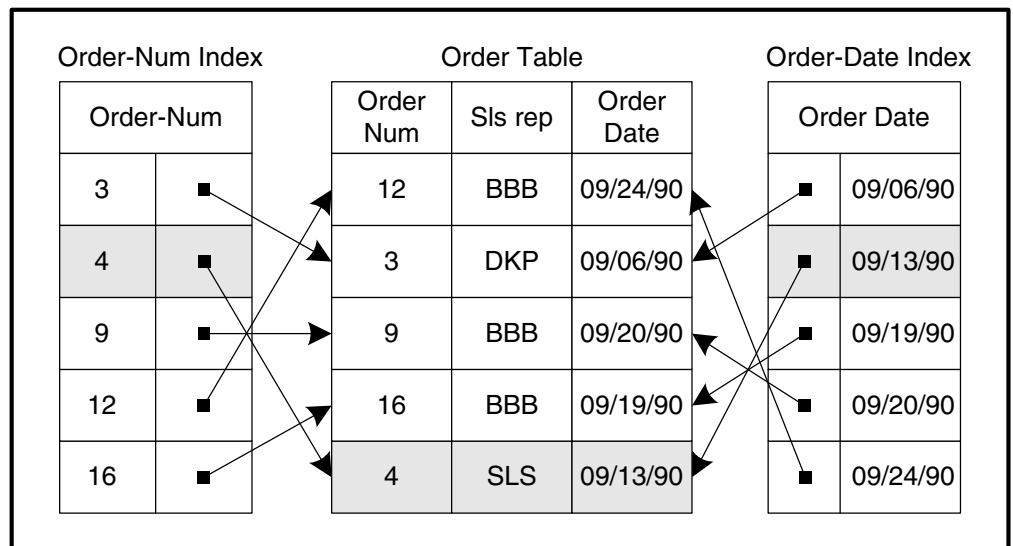

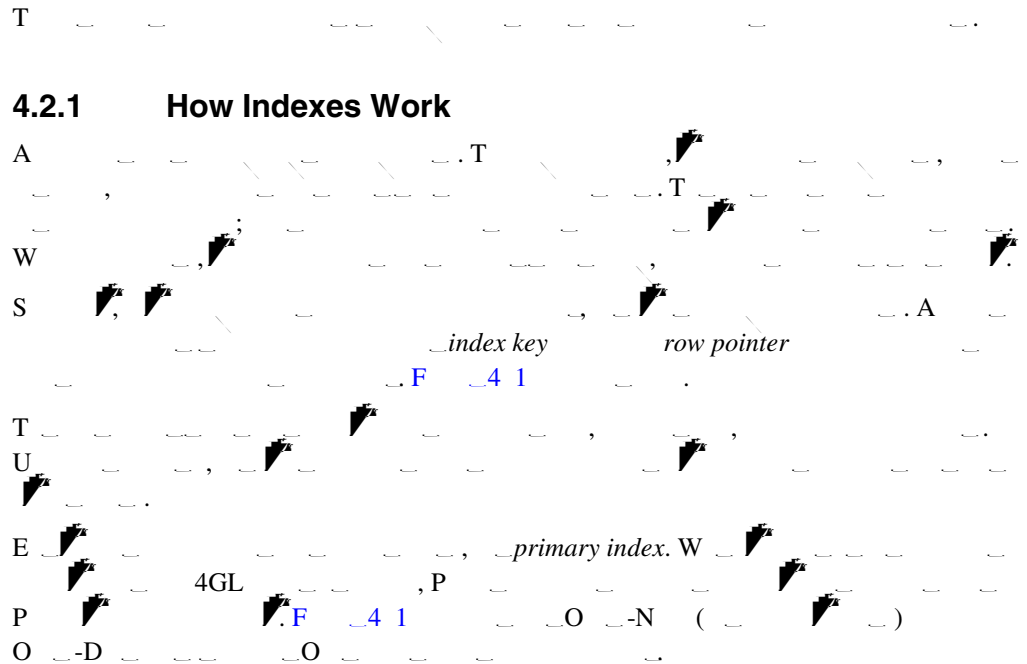

Figure 4-1: Indexing the Order Table

4.2.2 Why Define an Index?

	1. R 2. E (). 3. R			
			NO	NO
	Why the Index Was Defined:			
1. R				

4.2.4 Disadvantages of Defining an Index

Even though indexes can speed up data retrieval, they also have several disadvantages:

- Indexes take up extra space (Storage Cost Issues).
- Indexes slow down data insertion, update, and delete operations.

Therefore, you should only create an index when it is necessary to speed up data retrieval. For example, you should create an index on a column that is used in a WHERE clause of a query that is executed frequently.

4.3 Choosing Which Tables and Columns to Index

Indexes are used to speed up data retrieval. However, they also have several disadvantages. Therefore, you should only create an index when it is necessary to speed up data retrieval. For example, you should create an index on a column that is used in a WHERE clause of a query that is executed frequently.

You should also consider the size of the data. For example, if you have a table with 19,000 rows, it might be worth creating an index on a column that is used in a WHERE clause of a query that is executed frequently. However, if you have a table with 100 rows, it might not be worth creating an index on a column that is used in a WHERE clause of a query that is executed frequently.

4.4 Indexes and ROWIDs

A table with a primary key has a primary key index. The primary key index is a B-tree index. The primary key index is used to speed up data retrieval. The primary key index is also used to enforce the primary key constraint.

A table with a primary key has a primary key index. The primary key index is a B-tree index. The primary key index is used to speed up data retrieval. The primary key index is also used to enforce the primary key constraint.

A table with a primary key has a primary key index. The primary key index is a B-tree index. The primary key index is used to speed up data retrieval. The primary key index is also used to enforce the primary key constraint.

4.5 Calculating Index Size

Y

N * (6 +) * 2

F (T 4 2) 500 21

500 * (6 + 1 + 21) * 2 = 29,000
